D.5 Program FRICTION

FRICTION provides an estimate of laminar and turbulent skin friction suitable for use in aircraft preliminary design. It is an entirely new program, but has its roots in a program by Ron Hendrickson at Grumman. It runs on any computer. The input requires geometric information and either the Mach and altitude combination, or the Mach and Reynolds number at which the results are desired. The skin friction is found using the Eckert Reference Temperature method for laminar flow and the van Driest II formula for turbulent flow. The basic formulas are valid from subsonic to hypersonic speeds, but the implementation makes assumptions that limit the validity to moderate supersonic speeds (about Mach 3). The key assumption is that the vehicle surface is at the adiabatic wall temperature (the user can easily modify this assumption). Form factors are used to estimate the effect of thickness on drag, and a composite formula is used to include the effect of a partial run of laminar flow. Because the methods aren’t described in detail in the text, details are provided here.

Laminar flow

The approach used is known as the Eckert Reference Temperature Method, and this particular version is the one given by F.M. White in *Viscous Fluid Flow*, McGraw-Hill, New York, 1974, pp. 589-590. In this method the incompressible skin friction formula is used, with the fluid properties chosen at a specified reference temperature, which includes both Mach number and wall temperature effects.

First, assumptions are made for the fluid properties: Prandtl number, $Pr = 0.72$, Recovery factor, $r = Pr^{1/2}$, specific heat ratio, $\gamma = 1.4$, and edge temperature, $T_e = 390$ (°R). Then, for a given edge Mach number, $M_e$, and ratio of wall temperature to adiabatic wall temperature $T_W/T_{AW}$, compute:

$$\frac{T_W}{T_e} = \frac{T_W}{T_{AW}} \left(1 + r \frac{\gamma - 1}{2} M_e^2\right).$$

Remember that

$$T_{AW} = T_e \left(1 + r \frac{\gamma - 1}{2} M_e^2\right)$$

and then compute the reference temperature:

$$\frac{T^*}{T_e} \equiv .5 + .039 M_e^2 + 0.5 \left(\frac{T_w}{T_e}\right)$$

* These values can be changed easily by modifying the source code.
The Chapman-Rubesin constant based on the reference temperature and Sutherland’s viscosity law is then computed from:

\[ C^* = \left( \frac{T^*}{T_e} \right)^{1/2} \left( \frac{1 + K/T_e}{T^*/T_e + K/T_e} \right) \]

where \( K = 200°\text{R} \) for air.

Finally, the local friction coefficient \((\tau_w/q)\) is found from the standard Blasius formula, with \( C^* \) added,

\[ C_f = \frac{0.664\sqrt{C^*}}{\sqrt{\text{Re}_x}} \]

and

\[ C_F = 2C_f \]

which comes from

\[ C_F = \frac{F}{qx} = \frac{1}{x} \int_{x'}^{x} C_f(x') \, dx' \]

Recall that \( C_F \) accounts for one side of the plate only, so that if both sides are required for a drag estimate, then the skin friction coefficient, \( C_D' \), is twice \( C_F \) because the reference area is based on one side only, i.e., \( S_{\text{ref}} = 1/2 \, S_{\text{wet}} \).

Note that the results are not sensitive to the value of edge temperature for low Mach numbers, and therefore, an exact specification of \( T_e \) is not required. This method is implemented in subroutine \texttt{lamcf}.

**Turbulent flow**

For turbulent flow the so-called van Driest II Method is employed. This method was selected based on the recommendation of E.J. Hopkins and M. Inouye, contained in “An Evaluation of Theories for Predicting Turbulent Skin Friction and Heat Transfer on Flat Plates at Supersonic and Hypersonic Mach Numbers,” \textit{AIAA J.}, Vol. 9, No. 6, June 1971, pp. 993-1003. The particular algorithm is taken from NASA TN D-6945, “Charts for Predicting Turbulent Skin Friction From the Van Driest Method (II),” also by E.J. Hopkins, and dated October 1972.

Again, assumptions are made for the fluid properties: turbulent flow recovery factor, \( r = 0.88 \), specific heat ratio, \( \gamma = 1.4 \), and edge temperature, \( T_e = 222 \,(°\text{K}) \). Then, for a given edge Mach number, \( M_e \), and ratio of wall temperature to adiabatic wall temperature \( T_W/T_{AW} \) the calculation is started by computing the following constants:
\[ m = \frac{\gamma - 1}{2} M_e^2 \]

\[ F = \frac{T_w}{T_e} = \frac{T_w}{T_{AW}} \frac{T_{AW}}{T_e} \]

where

\[ \frac{T_{AW}}{T_e} = 1 + rm \]

\[ T_w = F \cdot T_e \]

\[ A = \left( \frac{rm}{F} \right)^{1/2} \]

\[ B = \frac{1 + rm - F}{F} \]

\[ \alpha = \frac{2A^2 - B}{\left( 4A^2 + B^2 \right)^{1/2}} \]

\[ \beta = \frac{B}{\left( 4A^2 + B^2 \right)^{1/2}} \]

\[ F_c = \frac{rm}{\left( \sin^{-1} \alpha + \sin^{-1} \beta \right)^2} \]

\[ = \left( \frac{1 + \sqrt{F}}{2} \right)^2 \]

\[ \text{if } M_e > 0.1 \]

\[ = \left( \frac{1 + \sqrt{F}}{2} \right)^2 \]

\[ \text{if } M_e \leq 0.1 \]

and

\[ F_\theta = \frac{\mu_e}{\mu_w} = \sqrt{\frac{1}{F}} \left( 1 + \frac{122}{T_w} \times 10^{-5} \right) \]

\[ \left( 1 + \frac{122}{T_e} \times 10^{-5} \right) \]

which is the Keyes viscosity law.

Finally,

\[ F_x = \frac{F_\theta}{F_c} \]

The analysis proceeds using barred quantities to denote “incompressible” variables, which are intermediate variables not used except to obtain the final results. Given the Reynolds number, \( Re \), an iteration is used to obtain the final results. Proceed as follows, finding...
now solve
\[
\frac{.242}{\sqrt{\overline{C}_F}} = \log\left(\overline{\text{Re}}_x \overline{C}_F \right)
\]
for \( \overline{C}_F \).

Use as an initial guess
\[
\overline{C}_F^0 = \frac{.074}{\overline{\text{Re}}_x^{.20}}.
\]

Then, Newton’s method is applied to the problem:
\[
f(\overline{C}_F) = 0 \Rightarrow \overline{C}_F^{i+1} = \overline{C}_F^i - \frac{f}{f'}
\]
which becomes for this equation:
\[
\overline{C}_F^{i+1} = \overline{C}_F^i \left[ 1 + \frac{.242 - \sqrt{\overline{C}_F^i} \log(\overline{\text{Re}}_x \overline{C}_F^i)}{.121 + \sqrt{\overline{C}_F^i} / \ln10} \right]
\]

Once this iteration is completed, and \( \overline{C}_F \) is known,
\[
C_F = \frac{\overline{C}_F}{F_c}
\]

Note that this value applies to one side of a plate only, so it must be doubled if the friction on both sides is desired to account for the proper reference areas. Here again, the results are not sensitive to the value of edge temperature for low Mach numbers, and the default value should be adequate for most cases. This formula is implemented in routine \texttt{turbcf}.

\textit{Composite formula}

When the flow is laminar and then transitions to turbulent, an estimate of the skin friction is available from a composite of the laminar and turbulent skin friction formulas using Schlichting’s formula (see T. Cebeci and P. Bradshaw, \textit{Momentum Transfer in Boundary Layers}, McGraw-Hill, New York, 1977, pp. 187). Given the transition position, \( x_c/L \) and \( \text{Re}_L \), compute
\[
\text{Re}_c = \left( \frac{x_c}{L} \right) \text{Re}_L
\]
and compute the laminar skin friction based on \( \text{Re}_c \) and the turbulent skin friction twice, based on both Reynolds numbers and then find the value that includes both laminar and turbulent flow from:
Several formulas are available, are all roughly equivalent, and have been evaluated extensively for incompressible flow. They are only approximate for compressible flow.

**Form factors**

To include the effects of thickness, it has been found that the skin friction formulas should be adjusted through the use of form factors. Two different factors are used in this code. For wing-like shapes,

\[
FF = 1.0 + 1.8 \left( \frac{t}{c} \right) + 50 \left( \frac{t}{c} \right)^4
\]

where \( t/c \) is the thickness ratio of of particular component. For bodies,

\[
FF = 1.0 + 1.5 \left( \frac{d}{l} \right)^{1.5} + 50 \left( \frac{d}{l} \right)^3
\]

where \( d/l \) is the ratio of diameter to length. This is the reciprocal of the fineness ratio.

**Program Operation:**

Running the program, you will be prompted for the name of an input data set, the maximum length is 15 characters. The output is sent to the screen, but can be sent to a file by changing the value of IWRIT to something other than 6 in the main program. The sample data case on the disk is F15.FRICTION.

</tbody>
</table>
   if FINMD = 0.0, this is the Altitude (in 1000 feet)
   if FINMD = 1.0, this is the Reynolds no. per unit length in millions

Note: Card 4 is repeated for each value of Mach and altitude desired. The program stops when either the end of the data is reached or a Mach number of zero is read.

Output: The input is echoed to allow for easy check of data and to keep all information together. Then the drag calculation for each \( M, h \) or \( M, Re/L \) is made. First, the reference areas, lengths, thicknesses, form factors and the transition position are output. These values are fixed for each combination of Mach and Reynolds number. Next, for each case the Reynolds number of each component and the basic skin friction are found. Then the skin friction times the wetted area and the skin friction times the wetted area and form factor are found. Finally, the latter is divided by the reference area and the contribution to the total drag in terms of a drag coefficient for the particular component, CDCOMP, is then found. These columns are summed, and the bottom value under the CDCOMP column is the total skin friction and form drag coefficient. After all the conditions are computed, a summary of results is presented as a table at the end of the output.
